Braina 2.1 was released on February 16, 2016. Braina is a smart assistant that uses deep neural networks to provide solutions to common user queries. It has millions of artificial neural networks that learn what each user wants, and then offer a suggested solution based on the data available to it. Braina was developed by The Machine Intelligence Department of Microsoft Research Cambridge. It has been developed in collaboration with SRI International and University of Cambridge. Braina's artificial neural networks are trained using internal and external data. It will use news articles, for example, to learn that the city of London is near the time zone of New York, which in turn helps to establish that it will be four in the afternoon there, at the same time as it is four in the afternoon here. Braina learns to understand its user over time and will use personal information about its user and queries to provide better and better responses. List of features Braina has the following features: Suggestions: braina makes recommendations based on its knowledge of its user and the user's behavior Actions: braina has a set of actions it can take to respond to queries The Braina desktop application: braina can be launched via Windows Task Manager. It will not begin to run unless the user has installed the official Braina Desktop Launcher. Once Braina is launched, it will ask to use the desktop or move to the

taskbar. Synonyms braina synonyms are those names that are commonly used to refer to it. The synonym selection is partially based on the results of N-gram analysis of the words which are part of the Braina Knowledge Base (KB). This is a set of data and information about user questions and the results of their processing. The data is prepared from several sources: queries submitted by the users, results returned by the search engines and the collection of news articles.

Braina does not use any kind of pattern matching to choose the synonyms. This means that, for example, a user querying for word1 or word2 may receive a different list of synonyms than if he or she was searching for word1/word2. The knowledge that is used by Braina to decide which is the best synonym is based on three factors: the frequency of a word in the set of words, whether it appears in the user's query in the context of Braina or not and the knowledge that it has about the language.
